

Saint Matthew Island Blue King Crab Stock Assessment 2016

D’Arcy Webber

Jie Zheng

James Ianelli

May 2016

Executive Summary

1. **Stock:** Blue king crab, *Paralithodes platypus*, Saint Matthew Island (SMBKC), Alaska.
2. **Catches:** Peak historical harvest was 9.454 million pounds (4288 tonnes) in 1983/84¹. The fishery was closed for 10 years after the stock was declared overfished in 1999. Fishing resumed in 2009/10 with a fishery-reported retained catch of 0.461 million pounds (209 tonnes), less than half the 1.167 million pound (529.3 tonnes) TAC. Following three more years of modest harvests supported by a fishery CPUE of around 10 crab per pot lift, the fishery was again closed in 2013/14 due to declining trawl-survey estimates of abundance and concerns about the health of the stock. The directed fishery resumed again in 2014/15 with a TAC of 0.655 million pounds (300 tonnes), but the fishery performance was relatively poor with the retained catch of 0.309 million pounds (140 tonnes).
3. **Stock biomass:** Following a period of low numbers after the stock was declared overfished in 1999, trawl-survey indices of SMBKC stock abundance and biomass generally increased in subsequent years, with survey estimated mature male biomass reaching 20.98 million pounds (9516 tonnes; CV = 0.55) in 2011, the second highest in the 37-year time series used in this assessment. Survey mature male biomass then declined to 12.46 million pounds (5652 tonnes; CV = 0.33) in 2012 and to 4.459 million pounds (2202 tonnes; CV = 0.22) in 2013 before going back up to 12.06 million pounds (5472 tonnes; CV = 0.44) in 2014 and 11.32 million pounds (5134 tonnes; CV = 0.76).
4. **Recruitment:** Because little information about the abundance of small crab is available for this stock, recruitment has been assessed in terms of the number of male crab within the 90-104 mm CL size class in each year. The 2013 trawl-survey area-swept estimate of 0.335 million male SMBKC in this size class marked a three-year decline and was the lowest since 2005. That decline did not continue with the 2014 survey with an estimate of 0.723 million. The survey recruitment is 0.992 million in 2015, but the majority of them came from one tow with a great deal of uncertainty.
5. **Management performance:** In recent assessments, estimated total male catch has been determined as the sum of fishery-reported retained catch, estimated male discard mortality in the directed fishery, and estimated male bycatch mortality in the groundfish fisheries, as these have been the only sources of non-negligible fishing mortality to consider.

The stock was above the minimum stock-size threshold (MSST) in 2014/15 and is hence not overfished. Overfishing did not occur.

6. **Basis for the OFL:** Estimated 15 February mature-male biomass (MMB_{mating}) is used as the measure of biomass for this Tier 4 stock, with males measuring 105 mm CL or more considered mature. The B_{MSY} proxy is obtained by averaging estimated MMB_{mating} over a specific reference time period, and current CPT/SSC guidance recommends using the full assessment time frame as the default reference period.

¹1983/84 refers to a fishing year from 1 July 1983 to 30 June 1984.

Table 1: Status and catch specifications (1000 tonnes) (scenario 1). MSST is minimum stock-size threshold, MMB is mature male biomass, TAC is total allowable catch, OFL is over fishing limit, ABC is the annual b catch.

Year	MSST	Biomass (MMB)	TAC	Retained catch	Total male catch	OFL	ABC
2011/12	1.50	5.03	1.15	0.85	0.95	1.70	1.54
2012/13	1.80	2.85	0.74	0.73	0.82	1.02	0.92
2013/14	1.50	3.01	0.00	0.00	0.00	0.56	0.45
2014/15	1.86	2.48	0.30	0.14	0.15	0.43	0.34
2015/16		2.45				0.28	0.22

A. Summary of Major Changes

Changes in Management of the Fishery

There are no new changes in management of the fishery.

Changes to the Input Data

All time series used in the assessment have been updated to include the most recent fishery and survey results. This assessment makes use of an updated full trawl-survey time series supplied by R. Foy in August 2015 (new time series), updated groundfish bycatch estimates based on 1999-2014 NMFS AKRO data also supplied by R. Foy, and the ADF&G pot survey data in 2015.

Changes in Assessment Methodology

This assessment is done using Gmacs. The model is based upon the 3-stage length-based assessment model first presented in May 2011 by Bill Gaeuman and accepted by the CPT in May 2012. The model was developed to replace a similar 4-stage model used prior to 2011.

There are several differences between the Gmacs assessment and the previous model. One of the major differences being that natural and fishing mortality are continuous within each season. Despite this structural difference in the model, the differences between these two methods is likely to be small.

Season length in Gmacs is controlled simply by changing the proportion of natural mortality that is applied each season. For example, in this assessment four seasons are defined and the proportion of natural mortality that is applied each season is 0.000, 0.440, 0.185, and 0.375 in the final season. In Gmacs the proportion of natural mortality that is applied each season is fixed (i.e. it does not change each year). The previous model allowed the proportion of natural mortality to change each year (i.e. in the second season it ranged from 0.05 to 0.18 before the year 2000 and was 0.44 after 2000).

Finally, in Gmacs the size transition matrix is a combination of the growth matrix and the molting probability. The growth matrix is derived from empirical molt increment data and the molting probability for each size class in the model is derived from an inverse logistic curve. Put simply, we cannot specify the size transition matrix directly, thus getting our size transition matrix to match that used in the previous model exactly was not possible. However, it is close:

$$\begin{bmatrix} 0.2056 & 0.6799 & 0.1144 \\ 0 & 0.3963 & 0.6037 \\ 0 & 0 & 1 \end{bmatrix} \quad (1)$$

Also see Figure 30.

Also, selectivity is fixed to match the previous model.

Further details of the Gmacs model and configuration used are provided in Appendix A (SMBKC Model Description).

Changes in Assessment Results

Changes in assessment results depend on model scenario. One of the Gmacs scenarios (Gmacs selex) provides a reasonably good match to the 2015 model assessment.

C. Introduction

Scientific Name

The blue king crab is a lithodid crab, *Paralithodes platypus* (Brant 1850).

Distribution

Blue king crab are sporadically distributed throughout the North Pacific Ocean from Hokkaido, Japan, to southeastern Alaska (Figure 1). In the eastern Bering Sea small populations are distributed around St. Matthew Island, the Pribilof Islands, St. Lawrence Island, and Nunivak Island. Isolated populations also exist in some other cold water areas of the Gulf of Alaska (NPFMC 1998). The St. Matthew Island Section for blue king crab is within Area Q2 (Figure 2), which is the Northern District of the Bering Sea king crab registration area and includes the waters north of Cape Newenham (58°39' N. lat.) and south of Cape Romanzof (61°49' N. lat.).

Stock Structure

The Alaska Department of Fish and Game (ADF&G) Gene Conservation Laboratory division has detected regional population differences between blue king crab collected from St. Matthew Island and the Pribilof Islands². NMFS tag-return data from studies on blue king crab in the Pribilof Islands and St. Matthew Island support the idea that legal-sized males do not migrate between the two areas (Otto and Cummiskey

²NOAA grant Bering Sea Crab Research II, NA16FN2621, 1997.

Figure 1: Distribution of blue king crab (*Paralithodes platypus*) in the Gulf of Alaska, Bering Sea, and Aleutian Islands waters. Shown in blue.

Figure 2: King crab Registration Area Q (Bering Sea).

1990). St. Matthew Island blue king crab tend to be smaller than their Pribilof conspecifics, and the two stocks are managed separately.

Life History

Like the red king crab, *Paralithodes camtschaticus*, the blue king crab is considered a shallow water species by comparison with other lithodids such as golden king crab, *Lithodes aequispinus*, and the scarlet king crab, *Lithodes couesi* (Donaldson and Byersdorfer 2005). Adult male blue king crab are found at an average depth of 70m (NPFMC 1998). The reproductive cycle appears to be annual for the first two reproductive cycles and biennial thereafter (cf. Jensen and Armstrong, 1989) and mature crab seasonally migrate inshore where they molt and mate. Unlike red king crab, juvenile blue king crab do not form pods, but instead rely on cryptic coloration for protection from predators and require suitable habitat such as cobble and shell hash. Somerton and MacIntosh (1983) estimated SMBKC male size at sexual maturity to be 77.0 mm carapace length (CL). Paul et al. (1991) found that spermatophores were present in the vas deferens of 50% of the St. Matthew Island blue king crab males examined with sizes of 40-49 mm CL and in 100% of the males at least 100 mm CL. Spermatophore diameter also increased with increasing CL with an asymptote at ~ 100 mm CL. They noted, however, that although spermatophore presence indicates physiological sexual maturity, it may not be an indicator of functional sexual maturity. For purposes of management of the St. Matthew Island blue king crab fishery, the State of Alaska uses 105 mm CL to define the lower size bound of functionally mature males (Pengilly and Schmidt 1995). Otto and Cummiskey (1990) report an average growth increment of 14.1 mm CL for adult SMBKC males.

Management History

The SMBKC fishery developed subsequent to baseline ecological studies associated with oil exploration (Otto 1990). Ten U.S. vessels harvested 1.202 million pounds in 1977, and harvests peaked in 1983 when 164 vessels landed 9.454 million pounds (Fitch et al. 2012; Table 1XX). The fishing seasons were generally short, often lasting only a few days. The fishery was declared overfished and closed in 1999 when the stock biomass estimate was below the minimum stock-size threshold (MSST) of 11.0 million pounds as defined by the Fishery Management Plan for the Bering Sea/Aleutian Islands King and Tanner crabs (NPFMC 1999). Zheng and Kruse (2002) hypothesized a high level of SMBKC natural mortality from 1998 to 1999 as an explanation for the low catch per unit effort (CPUE) in the 1998/99 commercial fishery and the low numbers across all male crab size groups caught in the annual NMFS eastern Bering Sea trawl survey from 1999 to 2005 (Table XX2a). In Nov 2000, Amendment 15 to the FMP for Bering Sea/Aleutian Islands king and Tanner crabs was approved to implement a rebuilding plan for the SMBKC stock (NPFMC 2000). The rebuilding plan included a regulatory harvest strategy (5 AAC 34.917), area closures, and gear modifications. In addition, commercial crab fisheries near St. Matthew Island were scheduled in fall and early winter to reduce the potential for bycatch mortality of vulnerable molting and mating crab.

NMFS declared the stock rebuilt on 21 September 2009, and the fishery was reopened after a 10-year closure on 15 October 2009 with a TAC of 1.167 million pounds, closing again by regulation on 1 February 2010. Seven participating vessels landed a catch of 460,859 pounds with a reported effort of 10,697 pot lifts and an estimated CPUE of 9.9 retained number of crab per pot lift. The fishery remained open the next three years with modest harvests and similar CPUE, but large declines in the NMFS trawl-survey estimate of stock abundance raised concerns about the health of the stock, prompting ADF&G to close the fishery again for the 2013/14 season. Due to abundance above thresholds, the fishery was reopened for the 2014/15 season with a low TAC of 0.655 million pounds and in 2015/16 the TAC was further reduced to 0.411 million pounds.

Though historical observer data are limited due to very limited sampling, bycatch of female and sublegal male crab from the directed blue king crab fishery off St. Matthew Island was relatively high historically, with estimated total bycatch in terms of number of crab captured sometimes twice or more as high as the catch of legal crab (Moore et al. 2000; ADF&G Crab Observer Database). Pot-lift sampling by ADF&G crab observers (Gaeuman 2013; ADF&G Crab Observer Database) indicates similar bycatch rates of discarded male crab

since the reopening of the fishery (Table 3XX), with total male discard mortality in the 2012/13 directed fishery estimated at about 12% (0.193 million pounds) of the reported retained catch weight, assuming 20% handling mortality. On the other hand, these same data suggest a significant reduction in the bycatch of females, which may be attributable to the later timing of the contemporary fishery and the more offshore distribution of fishery effort since re-opening in 2009/10³. Some bycatch of discarded blue king crab has also been observed historically in the eastern Bering Sea snow crab fishery, but in recent years it has generally been negligible, and observers recorded no bycatch of blue king crab in sampled pot lifts during 2013/14. The St. Matthew Island golden king crab fishery, the third commercial crab fishery to have taken place in the area, typically occurred in areas with depths exceeding blue king crab distribution. NMFS observer data suggest that variable but mostly limited SMBKC bycatch has also occurred in the eastern Bering Sea groundfish fisheries (Table 5XX).

D. Data

Summary of New Information

Data used in this assessment have been updated to include the most recently available fishery and survey numbers. In addition, this assessment makes use of an updated trawl-survey time series provided by R. Foy in August 2015 (new time series), as well as updated 1993-2014 groundfish bycatch estimates based on AKRO data also supplied by R. Foy. The data extent and availability used in each of the Gmacs models is shown in Figure 3).

Figure 3: Data extent for the SMBKC assessment.

³D. Pengilly, ADF&G, pers. comm.

Major Data Sources

Major data sources used in this assessment include annual directed-fishery retained-catch statistics from fish tickets (1978/79-1998/99, 2009/10-2012/13, and 2014/15; Table 1XX); results from the annual NMFS eastern Bering Sea trawl survey (1978-2015; Table 2XX); results from the triennial ADF&G SMBKC pot survey (every third year during 1995-2013) and 2015 pot survey (Table 2); size-frequency information from ADF&G crab-observer pot-lift sampling (1990/91-1998/99, 2009/10-2012/13, and 2014/15; Table XX3); and NMFS groundfish-observer bycatch biomass estimates (1992/93-2014/15; Table XX5). Figure 4 maps stations from which SMBKC trawl-survey and pot-survey data were obtained. Further information concerning the NMFS trawl survey as it relates to commercial crab species is available in Daly et al. (2014); see Gish et al. (2012) for a description of ADF&G SMBKC pot-survey methods. It should be noted that the two surveys cover different geographic regions and that each has in some years encountered proportionally large numbers of male blue king crab in areas where the other is not represented (Figure 5). Crab-observer sampling protocols are detailed in the crab-observer training manual (ADF&G 2013). Groundfish SMBKC bycatch data come from NMFS Bering Sea reporting areas 521 and 524 (Figure 6). Note that for this assessment the newly available NMFS groundfish observer data reported by ADF&G statistical area was not used.

Figure 4: Trawl and pot-survey stations used in the SMBKC stock assessment.

Table 2: Size-class and total CPUE (90+ mm CL) with estimated CV and total number of captured crab (90+ mm CL) from the 96 common stations surveyed during the six triennial ADF&G SMBKC pot surveys. Source: D. Pengilly and R. Gish, ADF&G.

Year	Stage-1 (90-104 mm)	Stage-2 (105-119 mm)	Stage-3 (120+ mm)	Total CPUE	CV	Number of crabs
1995	1.919	3.198	6.922	12.042	0.13	4624
1998	0.964	2.763	8.804	12.531	0.06	4812
2001	1.266	1.737	5.487	8.477	0.08	3255
2004	0.112	0.414	1.141	1.667	0.15	640
2007	1.086	2.721	4.836	8.643	0.09	3319
2010	1.326	3.276	5.607	10.209	0.13	3920
2013	0.878	1.398	3.367	5.643	0.19	2167
2015	0.198	0.682	1.924	2.805	0.18	1077

Other Data Sources

As with the most recent model configuration developed for this assessment, this version makes use of a growth transition matrix based on Otto and Cummiskey (1990). Other relevant data sources, including assumed population and fishery parameters, are presented in Appendix A, which provides a detailed description of the base-model configuration used for the 2012 and 2013 assessments.

Excluded Data Sources

Groundfish bycatch size-frequency data available for selected years, though used in the model-based assessment in place prior to 2011, play no direct role in this analysis. This is because these data tend to be severely limited: for example, 2012/13 data include a total of just 4 90-mm+ CL male blue king crab from reporting areas 521 and 524.

E. Analytic Approach

History of Modeling Approaches for this Stock

A four-stage catch-survey-analysis (CSA) assessment model was used before 2011 to estimate abundance and biomass and prescribe fishery quotas for the SMBKC stock (2010 SAFE; Zheng et al. 1997). The four-stage CSA is similar to a full length-based analysis, the major difference being coarser length groups, which are more suited to a small stock with consistently low survey catches. In this approach, the abundance of male crab with a CL of 90 mm or above is modeled in terms of four crab stages: stage 1: 90-104 mm CL; stage 2: 105-119 mm CL; stage 3: newshell 120-133 mm CL; and stage 4: oldshell \geq 120 mm CL and newshell \geq 134 mm CL. Motivation for these stage definitions comes from the fact that for management of the SMBKC stock, male crab measuring at least 105 mm CL are considered mature, whereas 120 mm CL is considered a proxy for the legal size of 5.5 in carapace width, including spines. Additional motivation for these stage definitions derives from an estimated average growth increment of about 14 mm per molt for SMBKC (Otto and Cummiskey 1990).

Concerns about the pre-2011 assessment model led to CPT and SSC recommendations that included development of an alternative model with provisional assessment based on survey biomass or some other index of abundance. An alternative 3-stage model was proposed to the CPT in May 2011 but was requested to proceed with a survey-based approach for the Fall 2011 assessment. In May 2012 the CPT approved a slightly revised and better documented version of the alternative model for assessment.

Assessment Methodology

The 2015 SMBKC stock assessment model, first used in Fall 2012, is a variant of the previous four-stage SMBKC CSA model (2010 SAFE; Zheng et al. 1997) and similar in complexity to that described by Collie et al. (2005). Like the earlier model, it considers only male crab at least 90 mm in CL, but it combines stages 3 and 4 of the earlier model resulting in just three stages (male size classes) determined by carapace length measurements of (1) 90-104 mm, (2) 105-119 mm, and (3) 120 mm+ (i.e., 120 mm and above). This consolidation was driven by concern about the accuracy and consistency of shell-condition information, which had been used in distinguishing stages 3 and 4 of the earlier model.

Each model year is split into four seasons.

A detailed description of the base model and its implementation in the software AD Model Builder (Fournier et al. 2012) is presented in Appendix A.

Model Selection and Evaluation

Four model scenarios were considered. In this document results from these models and the 2015 model are compared.

1. **2015 Model:** model output from 2015 provided by Jie.
2. **Gmacs base:** tries to match as closely as possible the 2015 Model.
3. **Gmacs selex:** directed pot, NMFS trawl survey and ADF&G pot survey selectivities are estimated for stage-1 and stage-2 crab.
4. **Gmacs CV:** Additional CV is estimated for the ADF&G pot survey.
5. **Gmacs M:** Natural mortality (M) is fixed at 0.18 yr^{-1} during all years.

Results

Preliminary results for the Gmacs configuration are provided here with comparisons to the 2015 model.

- a. Effective sample sizes.

Observed and estimated effective sample sizes are compared in Table XX.

- b. Tables of estimates.

Model parameter estimates are summarized in Tables 3, 4. Negative log likelihood values and management measures for the four Gmacs scenarios are compared in Table 5. Estimated abundances by stage and mature male biomasses are listed in Table XX for four scenarios.

Generally, scenarios with different molting probabilities or survey selectivities for two periods fit the data better. Scenarios with additional CV for the pot survey CPUE fit the trawl survey data better and result in higher abundance and biomass estimates in most recent years. Like the results in May 2015, large differences exist for estimated molting probabilities or survey selectivities during the two periods. Plausible biological reasons have not yet been found to explain large differences in molting probabilities. Estimated trawl survey selectivities > 1.0 for both stages 1 and 2 during 2000-2015 are also troublesome, but might be possible due to changes in crab spatial distributions, based on the examination on pot survey data presented by Doug Pengilly to the CPT in May 2015. Differences of estimated trawl survey selectivities between two periods decrease with scenarios 10-4, 10-3, 10-2, and 10-0. The high estimated trawl survey selectivities imply that the catchability of trawl surveys during recent years is greater than the assumed value of 1.0.

c. Graphs of estimates.

Estimated (and fixed) selectivities are compared in Figure 12 and molting probabilities are shown in Figure 13. The various model fits to total male (> 89 mm CL) trawl survey biomass are compared in Figure 14, and the fits to pot survey CPUE are compared in Figure 15. Standardized residuals of total male trawl survey biomass and pot survey CPUE are plotted in Figure 16. Fits to stage compositions for trawl survey, pot survey, and commercial observer data are shown in Figures 17, 18, and 19 for the all scenarios. Bubble plots of stage composition residuals for trawl survey, pot survey, and commercial observer data are shown in Figures 20, 21, and 22 for the Gmacs base model. Fits to retained catch biomass and bycatch death biomass are shown for all scenarios in Figure 23. Estimated recruitment and mature male biomass are compared in Figures 24 and 25, respectively.

Estimated trawl survey selectivities and molting probabilities are generally confounded. For example, the estimated lower molting probabilities after 1999 are associated with lower trawl survey selectivity estimates for scenario 8, and the assumed higher molting probabilities result in higher estimated trawl survey selectivities for scenario 10 (Figures XX and XX; Table XX). To reduce the confounding, molting probabilities are fixed at the values estimated from tagging data during the same period for scenarios 9, 10, and 11.

d. Graphic evaluation of the fit to the data.

Model estimated relative survey biomasses are different in each of the scenarios. Scenarios T, 0, 00, and 1 have relatively high biomass in the early period and during recent years (Figure 14). Scenarios 2 and 3 with constant molting probabilities and trawl survey selectivities over time and with an additional CV for the pot survey CPUE result in much higher biomass estimates in recent years; the trend of the biomass estimates also differ from other scenarios (Figure XX). Estimated pot survey CPUEs are also dependent on scenarios, and the difference among scenarios are very similar to the relative survey biomasses (Figure 15).

There are strong temporal patterns for residuals of total trawl survey biomass and stage composition data for scenarios T, 0, 00, 1, 2, and 3 (showing only scenario 3), and no apparent residual patterns occur for other scenarios with two levels of trawl selectivities or molting probabilities over time (Figures XX and XX). The stage compositions for observer data were not fit very well before 2000 for all scenarios, because the data are low quality and effective sample size is assumed small accordingly. The absolute values of standardized residuals of survey biomass are relatively smaller for scenarios 10-4, 10-3, 10-2, and 10-0 than those for scenario 10 (Figure XX). All scenarios fit well to retained catch biomass and fits to bycatch biomass are generally good.

Estimated recruitment to the model is variable over time (Figure 24). Estimated recruitment during recent years is generally low in all scenarios. Estimated mature male biomasses on 15 February also fluctuates strongly over time; the high biomass estimates in recent years for scenarios 2 and 3 show an opposite trend from the other scenarios (Figure 25).

e. Retrospective and historic analyses.

Gmacs does can not do retrospective analysis yet.

f. Uncertainty and sensitivity analyses.

Estimated standard deviations of parameters are summarized in Table 9XX for six scenarios. Probabilities for mature male biomass and OFL in 2015 are illustrated in the section “F. Calculation of the OFL”

g. Comparison of alternative model scenarios.

F. Calculation of the OFL and ABC

The overfishing level (OFL) is the fishery-related mortality biomass associated with fishing mortality F_{OFL} . The SMBKC stock is currently managed as Tier 4 (2013 SAFE), and only a Tier 4 analysis is presented here. Thus given stock estimates or suitable proxy values of B_{MSY} and F_{MSY} , along with two additional parameters α and β , F_{OFL} is determined by the control rule

$$F_{OFL} = \begin{cases} F_{MSY}, & \text{when } B/B_{MSY} > 1 \\ F_{MSY} \frac{(B/B_{MSY} - \alpha)}{(1 - \alpha)}, & \text{when } \beta < B/B_{MSY} \leq 1 \end{cases} \quad (2)$$

$F_{OFL} < F_{MSY}$ with directed fishery $F = 0$, when $B/B_{MSY} \leq \beta$

where B is quantified as mature-male biomass MMB_{mating} , at mating with time of mating assigned a nominal date of 15 February. Note that as B itself is a function of the fishing mortality F_{OFL} , in case b) numerical approximation of F_{OFL} is required. As implemented for this assessment, all calculations proceed according to the model equations given in Appendix A. In particular, the OFL catch is computed using equations A3, A4, and A5, with F_{OFL} taken to be full-selection fishing mortality in the directed pot fishery and groundfish trawl and fixed-gear fishing mortalities set at their model geometric mean values over years for which there are data-based estimates of bycatch-mortality biomass.

The currently recommended Tier 4 convention is to use the full assessment period, currently 1978-2015, to define a B_{MSY} proxy in terms of average estimated MMB_{mating} and to put $\gamma = 1.0$ with assumed stock natural mortality $M = 0.18 \text{ yr}^{-1}$ in setting the F_{MSY} proxy value γM . The parameters α and β are assigned their default values $\alpha = 0.10$ and $\beta = 0.25$. The F_{OFL} , OFL, and MMB in 2015 for 18 scenarios are summarized in Table 10XX. ABC is 80% of the OFL.

OFL, ABC, retained catch and bycatches for 2015 are summarized for scenarios 10 and 10-4 below:

G. Rebuilding Analysis

This stock is not currently subject to a rebuilding plan.

H. Data Gaps and Research Priorities

1. Growth increments and molting probabilities as a function of size.
2. Trawl survey catchability and selectivities.
3. Temporal changes in spatial distributions near the island.
4. Natural mortality.

I. Projections and Future Outlook

With the decline of estimated population biomass during recent years, outlook for this stock is not promising. If the decline continues, the stock will fall to depleted status soon.

J. Acknowledgements

We thank the Crab Plan Team, Doug Pengilly for reviewing the earlier draft of this manuscript. Some materials in the report are from the SAFE report prepared by Bill Gaeuman in 2014.

Figure 27: Distribution of carapace width (mm) at recruitment.

Figure 28: Growth increment (mm) each molt by sex in the OneSex and TwoSex models.

Figure 29: Probability of growth transition by stage. Each of the panels represent the stage before growth. The x-axes represent the stage after a growth (ignoring the probability of molting).

Figure 30: Probability of size transition by stage (i.e. the combination of the growth matrix and molting probabilities). Each of the panels represent the stage before a transition. The x-axes represent the stage after a transition.

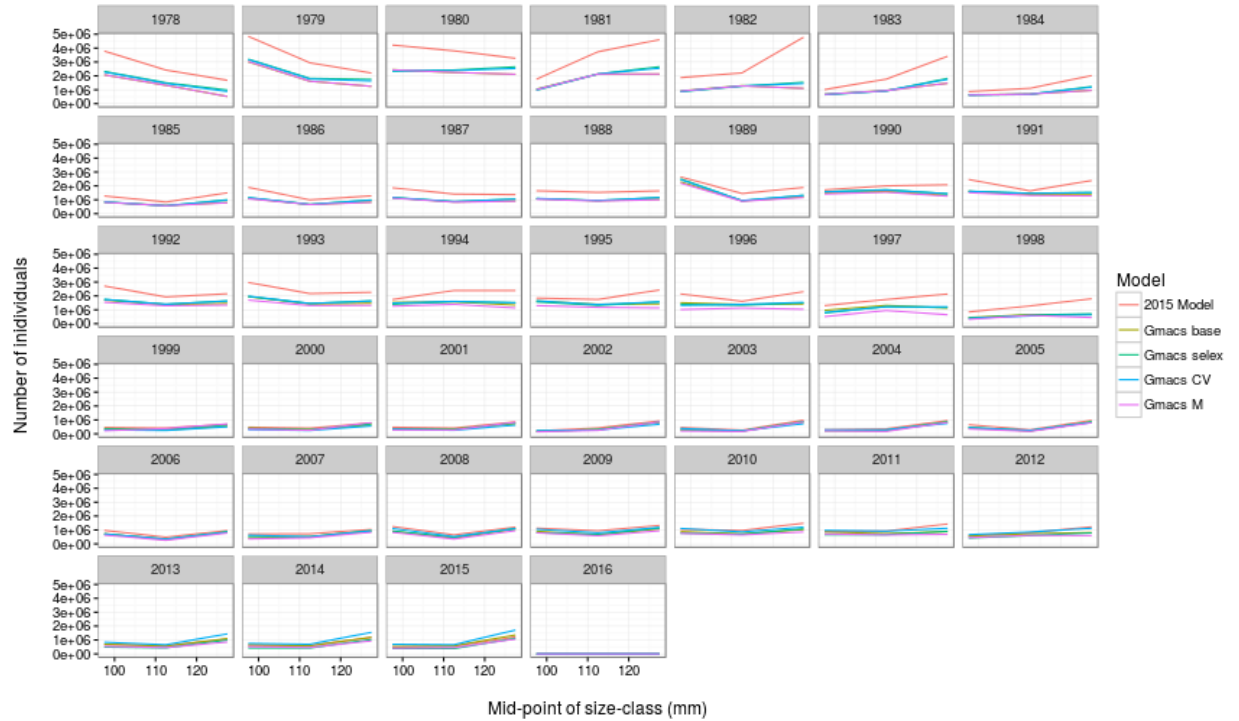

Figure 31: Numbers at length in 1953, 1975 and 2014 in each of the models. The first year of the OneSex model is 1953. The first year of the Zheng and TwoSex models in 1975.

Figure 32: Time-varying natural mortality (M_t). Estimated pulse period occurs in 1998 (i.e. M_{1998}).

Appendix A: SMBKC Model Description

1. Introduction

The Gmacs model has been specified to account only for male crab at least 90 mm in carapace length (CL). These are partitioned into three stages (size-classes) determined by CL measurements of (1) 90-104 mm, (2) 105-119 mm, and (3) 120+ mm. For management of the St. Matthew Island blue king crab (SMBKC) fishery, 120 mm CL is used as the proxy value for the legal measurement of 5.5 mm in carapace width (CW), whereas 105 mm CL is the management proxy for mature-male size (5 AAC 34.917 (d)). Accordingly, within the model only stage-3 crab are retained in the directed fishery, and stage-2 and stage-3 crab together comprise the collection of mature males. Some justification for the 105 mm value is presented in Pengilly and Schmidt (1995), who used it in developing the current regulatory SMBKC harvest strategy. The term “recruit” here designates recruits to the model, i.e., annual new stage-1 crab, rather than recruits to the fishery. The following description of model structure reflects the Gmacs base model configuration.

2. Model Population Dynamics

Within the model, the beginning of the crab year is assumed contemporaneous with the NMFS trawl survey, nominally assigned a date of 1 July. With boldface lowercase letters indicating vector quantities we designate the vector of stage abundances during season t and year y as

$$\mathbf{n}_{t,y} = [n_{1,t,y}, n_{2,t,y}, n_{3,t,y}]^T. \quad (3)$$

Using boldface uppercase letters to indicate a matrix, we describe the size transition matrix \mathbf{G}_t during season t as

$$\mathbf{G}_t = \begin{bmatrix} 1 - \pi_{12} - \pi_{13} & \pi_{12} & \pi_{13} \\ 0 & 1 - \pi_{23} & \pi_{23} \\ 0 & 0 & 1 \end{bmatrix}. \quad (4)$$

Similarly, the survival matrix $\mathbf{S}_{t,y}$ during season t and year y is

$$\mathbf{S}^{\text{df}} = \begin{bmatrix} s_1^{\text{df}} & 0 & 0 \\ 0 & s_2^{\text{df}} & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad (5)$$

where xx represents the combination of natural mortality (M) and fishing mortality (F). Recruitment of each stage to the model each season t and year y is represented as the vector $\mathbf{r}_{t,y}$ and may be defined using an inverse logistic curve.

The basic population dynamics underlying Gmacs can thus be described as

$$\begin{aligned} \mathbf{n}_{t+1,y} &= \mathbf{G}_t \mathbf{S}_{t,y} \mathbf{n}_{t,y} + \mathbf{r}_{t,y}, \text{ if } t < T \\ \mathbf{n}_{t,y+1} &= \mathbf{G}_t \mathbf{S}_{t,y} \mathbf{n}_{t,y} + \mathbf{r}_{t,y}, \text{ if } t = T \end{aligned} \quad (6)$$

where the scalar factor e^{-M_t} accounts for the effect of year- t natural mortality M_t and the hypothesized with π_{jk} equal to the proportion of stage- j crab that molt and grow into stage k from any one year to the next. The vector $N_{\text{new}} + 1 = [N_{\text{new1}}, t + 1, 0, 0]T$ registers the number $N_{\text{new1}}, t + 1$ of new crab, or “recruits”, entering the model at the start of year $t + 1$, all of which are assumed to go into stage 1. Aside from natural mortality and molting and growth, only the directed fishery and some limited bycatch mortality

in the groundfish fisheries are assumed to affect the stock. Nontrivial bycatch mortality with another fishery, as occurred in 2012/13, is assumed to be accounted for in the model in the estimate of groundfish bycatch mortality.) The directed fishery is modeled as a mid-season pulse occurring at time π_t with full-selection fishing mortality F_t relative to stage-3 crab. Year- t directed-fishery removals from the stock are computed as

$$R_t^{df} = H^{df} S^{df} (1 - e^{F_t^{df}}) e^{-\tau_t M} N_t$$

where the diagonal matrices

and

$$\mathbf{H}^{df} = \begin{bmatrix} h^{df} & 0 & 0 \\ 0 & h^{df} & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (7)$$

account for stage selectivities s_1^{df} and s_2^{df} and discard handling mortality h^{df} in the directed fishery, both assumed constant over time. Yearly stage removals resulting from bycatch mortality in the groundfish trawl and fixed-gear fisheries are calculated as Feb 15 (0.63 yr) pulse effects in terms of the respective fishing mortalities F_t^{gt} and F_t^{gf} by

3. Model Data

Data inputs used in model estimation are listed in Table 1XX. All quantities relate to male SMBKC ≤ 90 mm CL.

4. Model Parameters

Estimated parameters with scenarios 8 and 10 are listed in Table 2XX and include an estimated parameter for natural mortality (M) in 1998/99 assuming of an anomalous mortality event in that year, as hypothesized by Zheng and Kruse (2002), with natural mortality otherwise fixed at 0.18 yr^{-1} .

In any year with no directed fishery, and hence zero retained catch, F_t^{df} is set to zero rather than model estimated. Similarly, for years in which no groundfish bycatch data are available, F_t^{gf} and F_t^{gt} are imputed to be the geometric means of the estimates from years for which there are data. Table 3XX lists additional externally determined parameters used in model computations.

For scenarios 0 and 1, the stage-transition matrix is

$$\begin{bmatrix} 0.2 & 0.7 & 0.1 \\ 0 & 0.4 & 0.6 \\ 0 & 0 & 1 \end{bmatrix} \quad (8)$$

which includes molting probabilities. For scenarios 3-11, the growth matrix with molting crab is

$$\begin{bmatrix} 0.11 & 0.83 & 0.06 \\ 0 & 0.11 & 0.89 \\ 0 & 0 & 1 \end{bmatrix} \quad (9)$$

The combination of the growth matrix and molting probabilities results in the stage-transition matrix for scenarios 3-11. Molting probability for stage 1 for scenarios 8, 9, 10, 11 during 1978-2000 is assumed to be 0.91 estimated from the tagging data and ratio of molting probabilities of stages 2 to stage 1 is fixed as 0.69231 from the tagging data as well. For scenarios 0 and 1, stage-transition matrix

Both surveys are assigned a nominal date of 1 July, the start of the crab year. The directed fishery is treated as a season midpoint pulse. Groundfish bycatch is likewise modeled as a pulse effect, occurring at the nominal time of mating, Feb 15, which is also the reference date for calculation of federal management biomass quantities.

Table 7: Model bounds.

Parameter	LB	UB	Initial value	Prior type	p1	p2	Phaze
$\log(R_0)$	13.60	13.60	13.60	13.60	13.60	13.60	13.60
$\log(\bar{R})$	13.69	13.69	13.69	13.69	13.69	13.69	13.69
$\log(N_1)$	14.62	14.62	14.62	14.62	14.62	14.62	14.62
$\log(N_2)$	14.18	14.18	14.18	14.18	14.18	14.18	14.18
$\log(N_3)$	13.82	13.82	13.82	13.82	13.82	13.82	13.82
q_{pot}	-1.37	-1.37	-1.37	-1.37	-1.37	-1.37	-1.37

5. Model Objective Function and Weighting Scheme

The objective function consists of a sum of eight “negative loglikelihood” terms characterizing the hypothesized error structure of the principal data inputs with respect to their true, i.e., model-predicted, values and four “penalty” terms associated with year-to-year variation in model recruit abundance and fishing mortality in the directed fishery and groundfish trawl and fixed-gear fisheries. See Table 2, where upper and lower case letters designate model-predicted and data-computed quantities, respectively, and boldface letters again indicate vector quantities. Sample sizes n_t (observed number of male SMBKC ≤ 90 mm CL) and estimated coefficients of variation $\hat{c}v_t$ were used to develop appropriate variances for stage-proportion and abundance-index components. The weights λ_j appearing in the objective function component expressions in Table 2 play the role of “tuning” parameters in the modeling procedure.

Table 4XX. Loglikelihood and penalty components of base-model objective function. The λ_k are weights, described in text; the $n_{eff\ t}$ are effective sample sizes, also described in text. All summations are with respect to years over each data series.

Component	Distribution	Form
Legal retained-catch biomass	Lognormal	$-0.5 \sum (\log(c_t/C_t)^2 / \log(1 + cv_c^2))$
Dis. Pot bycatch biomass	Lognormal	

6. Estimation

The model was implemented using the software AD Model Builder (Fournier et al. 2012), with parameter estimation by minimization of the model objective function using automatic differentiation. Parameter estimates and standard deviations provided in this document are AD Model Builder reported values assuming maximum likelihood theory asymptotics.
